Parafermions on quantum Hall edges: towards topological qubits

Parafermions are a fractionalization of Majorana zero modes [1,2], similarly to how Laughlin quasiparticles are a fractionalization of electrons. While Majoranas are considered the most promising candidate for implementing topologically protected qubits, parafermions are topologically protected as well and offer the advantage of a larger Hilbert space.

I will start with an introduction to creating parafermionic zero modes at quantum Hall edges and then discuss how a qubit can be built based on parafermions (focusing on how qubit measurement and manipulation can be performed) [3]. I will conclude with an example of how the same parafermionic qubit device can be used as a physics playground, not related to quantum computing [4].
